Worthing Brighton Bus

Passengers deserve one network. This one is built from open data.

On this coast, four bus companies run four apps and their own day tickets, and two councils plan up to a line through Portslade. This proof of concept joins it all up from the government's open bus data, and measures how the buses really run.

Try it live:

Step 1 of 8 · Published timetable, week of 2 November 2026

What passengers face today

Four operators each run their own apps and tickets. With a council boundary through the community, services in the west are weaker on every measure.

- Weekday departures per stop: 64.9 west of the line against 99.7 east, in a band 4 km either side (65%).
- Routes on a weekday: 20 against 39. On Saturday 11 against 25; on Sunday 9 against 22.
- Departures after 11pm on a weekday: 581 west of the line against 1,376 east.
- Lancing and South Portslade, about five miles apart on the same coast road: 32.8 against 121.7 weekday departures per stop.
- Joint working pays: up to 43% more passengers on the two routes the councils improved together. The coast west of Portslade wasn't one of them.

Step 2 of 8 · Live

The network as people use it

Each operator's buses on one map and one departure board. Every operator's ticket zones in one place, and a cross-operator journey checker.

- Every operator on one departure board: at St Peter's Church in Brighton, Brighton & Hove, Metrobus, Stagecoach and Compass departures are listed together, with live times marked.
- Every operator's day-ticket zones on one map, and a checker that finds the cheapest ticket that covers a whole journey, across companies.
- Door-to-door planning across operators, still experimental.

Step 3 of 8 · Recorded: 34 days, 27 September to 31 October

What the buses actually did

The same open feed, kept: real journey times, where buses lose time, and how reliable each route is, published for anyone to check.

- Each minute the live feed is saved, and each bus is matched to the timetabled journey it is running.
- Journey times between any two stops, by day and time of day, with the slow end shown as well as the usual.
- A delay map of where buses lose time against the timetable; a stretch is only coloured once it has enough journeys behind it.
- Gaps in the record are listed, not hidden: 18 October.

Beyond the baseline

ABOD, the Department's free analytics service, is for bus operators and local authorities, by invitation. This is for everyone: the same kind of evidence, plus passenger tools, under an open licence.

- Anyone can open it: no login, no invitation. Councillors, passengers and journalists see the same figures.
- It joins the evidence to the passenger side: live times for every operator, every operator's ticket zones, and the cheapest ticket across them.
- ABOD matches a bus to its journey by the operator's journey reference and skips it when that does not match the timetable. This site tries three ways, reads the trip feed as well as the location feed, and names 97% of tracked journeys by the operator's own feed.
- ABOD's code can be read on GitHub, but its licence lets only KPMG firms reuse it. This site's code is MIT-licensed: anyone may copy it.

Sources: Analyse Bus Open Data (RTIG); ABOD's matching method (OTP Matching); ABOD's licence.

Public money, public return

The data is free from the Bus Open Data Service; everything else costs under £20 a year. Because the code is open, any developer can build a complete bus information site for their area, showing the whole network across every operator, where each operator's own app and website cover only its own buses.

- Every figure on this site is built on that data, on free hosting, for under £20 a year: the cost of the web address.

Sources: Bus Open Data Service: "free open data, and does not require a licence"; Render: the free instance type the live data runs on.

Step 6 of 8 · Recorded and replayed

How far to trust it

Every figure says what it was divided by, how it was made, and what would make it wrong.

- As the board actually showed them, minute by minute, on ordinary days 79% of live times were within RTIG's window, and 86% of departures had a live time 15 minutes before they were due. We publish how often we are wrong, nightly, on the live data health page.
- Good to about a minute, not a second; fewer than 10 journeys over 5 days shows "too few", never a number.
- 97% of 133,615 tracked journeys are matched to their journey by the operator's own feed.
- We are timing buses by hand to check our stop times; the result will be published here.
- A bus we did not see is "missing", never "cancelled": its tracker may simply have been off.

Sources: Live estimates judged by RTIG's windows: 28 recorded days replayed (25 October 2026); What the board showed, rebuilt minute by minute (25 October 2026).

What one coast shows

If one volunteer can do this for one coast, an authority or a partner can do it for a region. The template is coming; the code is already open.

- The data is national; only the questions are local.
- Open by default: MIT-licensed code, CC BY words and data, and every day's evidence archived in public.
- A template for other regions is on the way, and a company that wants to develop this further would have full support.

Step 8 of 8 · Get in touch

Let's build it together

The code is open and the data is public. Operators: check our figures. Councils: plan the coast as one corridor. Technology firms and other regions: help turn this into a template.
